Agents Used For Moderate Sedation

- Benzodiazepines
  - Most widely used drug for Sedation
  - Probably work in limbic system and amygdala of the brain, where fear, anxiety and apprehension arise.
  - When Benzodiazepines come to these receptors from the blood stream, they go into the receptor sites and cause specific effects:

Copyright Ron Eslinger 2006
**Benzodiazepines**

**Effects**

- anxiolysis ... reduction of anxiety
- amnesiac ... makes patient have antero-grade amnesia (not retrograde)
- anti-convulsive ... stops seizures
- skeletal muscle relaxation
- sedative - hypnotic in large doses
- patients who chronically take Cimetidine (Tagamet) or Ranitidine (Zantac) are especially susceptible to Benzodiazepine overdose these H-2 blocking drugs may dramatically increase the sedative of even small doses of Benzodiazepine.

Copyright Ron Eslinger 2006
BENZODIAZEPINES

- Sedative hypnotic
- No analgesic properties
- Useful for seizures
BENZODIAZEPINES (2)

- Little respiratory or cardiovascular depression when used alone, but synergistic effects seen when combined with other CNS depressants
- Avoid use in pregnancy, alcohol intoxication, glaucoma, other CNS depressants
MIDAZOLAM (VERSED)

- Most commonly used sedative used for conscious sedation
- 3-5 times more potent than diazepam
- Rarely precipitates or causes pain on injection (as valium will)
**Midazolam (2)**

Titrated to effect in 0.5 mg increments

**Diazepam (Valium)**

- Used less than Midazolam
- Titrate in 2.5mg increments
- Incompatible with other agents, easily precipitates
Diazepam (2)

- Painful on injection
- Peak effect in less than 10 minutes
- Long half-life due to metabolites

Reversal for Benzodiazepines

- **Flumazenil (Romazicon)** (Specific Benzodiazepine antagonist)

- **Initial Dose:** 0.2 mg

- **Administration Technique:**
  - **Phase One:** Initially 0.2 mg IV over 15 seconds. If patient does not reach desired level of consciousness after 45 seconds.
  - **Phase Two:** Repeat dose at one minute intervals until a cumulative dose of 1mg has been administered (this includes initial dose in phase one).

Copyright Ron Eslinger 2006
Reversal for Benzodiazepines

Peak effect:

- 6 to 10 minutes
- 80% of the maximum response is seen within 3 minutes.
- Anesthesia should be involved if there is no desired clinical response with the administration of the initial 1 mg dose.
Reversal for Benzodiazepines

- Potential Adverse Reactions:
  - nausea, vomiting, sweating, hot flashes, agitation, headache, injection site pain
  - do not use Flumazenil in patients who chronically take Benzodiazepines.

- May precipitate:
  - tremors
  - profuse sweating
  - hypotension
  - seizure activity
**Flumazenil (Romazicon)**

- **Indications**: reversal of benzodiazepines’ effects - sedation, respiratory depression, amnesia
- **Dose**: 0.2 mg IV initially, titrate to effect
- **Caution** in patients with seizure disorders - may reverse effects of anti-seizure medications

Narcotics

- (commonly given along with Benzodiazepines)
- are great potentiators of respiratory depression when mixed. (great synergistic effect)

Most Common

- Morphine
- Fentanyl
- Demerol
Opioids

- No amnestic effects
- Provide analgesia and sedation
- Adverse reactions:
  - Respiratory depression
  - Nausea and vomiting
  - Pruritis, urticaria
  - Urinary retention (young males)
  - Constipation
Morphine

- Dose is up to 0.15 mg/kg
- Peak effect in 5-20 minutes, onset time less than one minute, duration 2-7 hours.
- Possible histamine release, all of opioid side effects most possible with morphine.
## Morphine

Meperidine (Demerol)

- One tenth the potency of morphine
- IV dose is 0.5-1.0 mg/kg
- Onset in less than one minute, peak effect in 5-20 minutes, duration 2-4 hours.
- Caution in patients with renal/hepatic impairment, Monoamine oxidase inhibitors (MAOIs) (used for depression, isoniazid (TB Treatment))
# Meperidine (Demerol)

</tr>
</tbody>
</table>
**Fentanyl (Sublimaze)**

- 75-100 times more potent than morphine
- Dose 0.7-1mcg/kg
- Onset within 30 seconds, peak effect in 5-15 minutes, duration of effects 30-60 minutes
- Titrate in 25 mcg increments
# Fentanyl (Sublimaze)

</tr>
</tbody>
</table>
Naloxone (Narcan)

- Dose: 0.5-1.0 mcg/kg
- All opioid effects, inclusive of analgesia, are reversed
- Titrate to effect
- Avoid rapid reversal - can lead to untoward sympathetic discharge, extreme pain, anxiety, pulmonary edema

Ketamine (Ketalar)

- Dissociative anesthetic/analgesic agent
- Derivative of phencyclidine (PCP)
- Excellent analgesic and amnestic
Ketamine (2)

- Indications: Short term procedures requiring intense analgesia
- Given IV by the operator, monitored by the monitor
- Contraindications: many

Copyright Ron Eslinger 2006
Ketamine (3)

Contraindications:

• Increased ICP (increases ICP)
• Corneal lacerations (increases intraocular pressure)
• Children with active URI (stimulates oral secretions), psychiatric disorders (may cause extreme mood alteration), compromised airways (may induce apnea/anesthesia)

Copyright Ron Eslinger 2006
Ketamine(4)

- **Recommended dosages:** 0.25-0.5 mg/kg IV, 1-2 mg/kg IM

- **Onset of action:** IV <30 sec, IM 5-20 min; peak effect IV 1 min, IM 3-4 min; duration of action IV 5-15 min, IM 12-25 min

Propofol

DIPRIVAN (Propofol) is an intravenous sedative-hypnotic agent commercially introduced in the United States in 1989 by Zeneca Pharmaceuticals. It was the first of a new class of intravenous anesthetic agents - the alkylphenols.

Dosage/Administration – **Adult dose**: 25 – 50mg (0.5 – 1 mg/kg) IV, administered in 10 mg increments over several minutes. Pain on injection is decreased with IV lidocaine, 0.1 mg/kg, added to the diprivan emulsion. Strict aseptic technique must be maintained in handling, as diprivan is preservative free and will support bacterial growth. Diprivan injection should be prepared for single patient use only, just prior to the initiation of each procedure. Discard after opened for 6 hours.

**Pediatric dose**: 0.5 – 1.0mg/kg infused slowly and titrated to desired effect.
Adverse Reactions

- Respiratory effects – respiratory depression, apnea, hiccup, bronchospasm, laryngospasm
- Cardiovascular effects – hypotension, arrhythmia, tachycardia, bradycardia, hypertension
- CNS effects – headache, dizziness, euphoria, myoclonic/clonic movement, seizures, sexual illusions.
Emergency Medications

- **Atropine**: Increases heart rate by blocking vagal nerve stimulation. IV bolus 0.4-1.0 mg.

- **Lidocaine**: Drug of choice for ventricular dysrhythmias - decreases automaticity. IV bolus 50-100 mg.

- **Ephedrine**: Increases blood pressure and heart rate by indirect cardiac stimulation. IV bolus 5-10 mg.
